Section 1

Clustering

Classification VS Clustering

Clustering main points

- Clustering is often used for data exploration or as a precursor to supervised learning methods.
- Like visualisation, it's more iterative and interactive, and less automated than supervised methods.
- Different clustering algorithms will give different results. You should consider different approaches, with different numbers of clusters.
- There are many heuristics for estimating the best number of clusters.
 Again, you should consider the results from different heuristics and explore different numbers of clusters.

Grouping countries based on protein consumption

A small dataset from 1973 on protein consumption

 9 food groups, 25 countries in Europe https://github.com/WinVector/zmPDSwR/tree/master/Protein/

```
path <- '../../data v2/Protein/'
df <- read.table(paste0(path, 'protein.txt'), sep='\t', header=TRUE)</pre>
str(df)
   'data.frame': 25 obs. of 10 variables:
##
    $ Country : chr "Albania" "Austria" "Belgium" "Bulgaria" ...
    $ RedMeat
             : num 10.1 8.9 13.5 7.8 9.7 10.6 8.4 9.5 18 10.2 ...
##
## $ WhiteMeat: num 1.4 14 9.3 6 11.4 10.8 11.6 4.9 9.9 3 ...
## $ Eggs : num 0.5 4.3 4.1 1.6 2.8 3.7 3.7 2.7 3.3 2.8 ...
   $ Milk : num
                     8.9 19.9 17.5 8.3 12.5 25 11.1 33.7 19.5 17.6 ...
##
## $ Fish : num
                     0.2 2.1 4.5 1.2 2 9.9 5.4 5.8 5.7 5.9 ...
    $ Cereals : num 42.3 28 26.6 56.7 34.3 21.9 24.6 26.3 28.1 41.7 ...
##
## $ Starch
             : num 0.6 3.6 5.7 1.1 5 4.8 6.5 5.1 4.8 2.2 ...
   $ Nuts : num 5.5 1.3 2.1 3.7 1.1 0.7 0.8 1 2.4 7.8 ...
##
    $ Fr. Veg : num 1.7 4.3 4 4.2 4 2.4 3.6 1.4 6.5 6.5 ...
```

Units and Scaling

- Units (or more precisely, disparity in units) affect the clustering result, e.g.,
 - height in feet and weight in pounds will give different distances and possibly different clusters – than if height in meters and weight in kilograms are used.
- Ideally, a unit of change in each coordinate should represent the same degree of difference
 - Animal-based food sources in general have more grams of protein per serving than plant-based food sources;
 - A change in consumption of 5 grams is a bigger difference in terms of vegetable consumption than it is in terms of red meat consumption.

Make clustering more coordinate-free

A general practice is to transform all the columns to have a mean value of 0 and a standard deviation of 1.

The scale() function in R

- returns a matrix as output, and
- annotates its output with two attributes.

```
vars.to.use <- colnames(df)[-1] # all column names except for the 1st column
scaled_df <- scale(df[,vars.to.use]) # this is a 25-by-9 matrix where each
# column has 0 mean and unit standard deviation</pre>
```

Make clustering more coordinate-free (cont.)

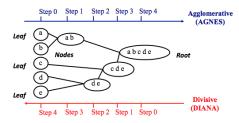

```
# The scaled:center attribute (a vector of 9 elements) contains the mean values
# of all the columns.
attr(scaled df, "scaled:center")
## RedMeat WhiteMeat Eggs
                                                 Cereals Starch
                               Milk Fish
                                                                    Nuts
## 9.828 7.896 2.936 17.112 4.284 32.248 4.276
                                                                     3.072
# The scaled:scale attribute (a vector of 9 elements) contains the variances
# of all the columns.
attr(scaled_df, "scaled:scale")
                        Eggs Milk Fish Cereals Starch
## RedMeat WhiteMeat
                                                                     Nuts
## 3.347078 3.694081 1.117617 7.105416 3.402533 10.974786 1.634085 1.985682
# The following also work:
attributes(scaled_df) $ scaled:center
attributes(scaled df) $ scaled:scale
```

Section 2

Hierarchical Clustering

Intuition Behind Hierarchical Clustering

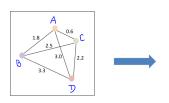

We can follow either the **agglomerative** (bottom-up) or **divisive** (top-down) way of clustering.

- Agglomerative clustering will start with n clusters, where n is the number of observations, and then group the most similar ones together.
- **Divisive clustering** will go the other way around assuming all your *n* data points are one big cluster, and then dividing most dissimilar ones into separate groups.

Hierarchical Clustering Illustration

	Α	В	С	D	
Α	0	1.8	0.6	3.0	
В	1.8	0	2.5	3.3	
С	0.6	2.5	0	2.2	
D	3.0	3.3	2.2	0	

If distances are not equal between points we can draw a "hanging tree" to illustrate distances

The result of a cluster analysis is a tree or dendrogram

Methods for grouping

- Nearest Neighbour Method creates groups by starting with points that are close together (having smallest distances) and build branches
 - In effect we keep asking the data matrix "Which point is my nearest neighbour?" to add branches
- Centroid Method creates a group based on points having the smallest distance to the group centroid rather than group member
 - First creates a group based on small distance then uses the centroid of that group to find which additional points belong in the same group
- Ward's Method creates groups such that variance is minimised within clusters
 - Looks for spherical clusters

Hierarchical Clustering using hclust()

The hclust() function:

- Input: a distance matrix (an object of class dist), which records the
 distances between all pairs of points in the data (using any one of the
 distance metrics).
- Output: a dendrogram a tree that represents the nested clusters.
- A variety of clustering methods can be used to produce a tree that records the nested cluster structure.

Compute the pairwise distances using dist()

dist() will calculate distance functions using

- the (squared) Euclidean distance (method="euclidean"),
- the Manhattan distance (method="manhattan"), and
- something like the Hamming distance, when categorical variables are expanded to indicators (method="binary").

If you want to use another distance metric, you'll have to compute the appropriate distance matrix and convert it to a dist object using the as.dist().

dist() returns an object of class 'dist', which includes the pairwise
Euclidean distances of the 25 observations. In this case, we have

The output of dist() function

Dr. Mubashar Hassan (Department of Com

```
# 25-choose-2 pairs (i.e., 25*24/2 = 300). So 300 Euclidean distance values
# are stored in variable `d` for further operation.
(d <- dist(scaled df, method="euclidean"))</pre>

Hierarchical Clustering

Semester 2, 2024

15 / 41

Clustering using hclust()

```
pfit <- hclust(d, method="ward.D2") # perform hierarchical clustering</pre>
# To examine `pfit`, type: summary(pfit) and pfit$height
plot(pfit, labels=df$Country, main="Cluster Dendrogram for Protein Consumption")
rect.hclust(pfit, k=5)  # k=5 means we want rectangles to be put around 5 clusters
xx \leftarrow c(3, 7.5, 13.5, 19.5, 23.5); yy \leftarrow -3.5; clusterID \leftarrow c(3,4,2,1,5)
text(xx, yy, clusterID, col="red")
```

Extract members of each cluster using cutree()

cutree() takes in a clustering model (e.g., created by hclust()) and
returns a vector (or matrix) of cluster group assignment(s) for each row.
We can specify the desired number(s) of groups (using the keyword
argument k) or the desired height value(s) (using the keyword argument h)
where the tree should be cut.

```
groups <- cutree(pfit, k=5)
groups
## [1] 1 2 2 1 3 4 3 4 2 5 3 2 5 2 4 3 5 1 5 4 2 2 3 2 1

print_clusters <- function(df, groups, cols_to_print) {
   Ngroups <- max(groups)
   for (i in 1:Ngroups) {
        print(paste("cluster", i))
        print(df[groups == i, cols_to_print])
      }
}</pre>
```

Extract members of each cluster using cutree() (cont.)

```
cols_to_print <- c("Country", "RedMeat", "Fish", "Fr.Veg")</pre>
print_clusters(df, groups, cols_to_print)
## [1] "cluster 1"

                   8.4 5.4
```

Grouping interpretation

We observe that the countries in each cluster tend to be in the same geographical region.

It makes sense that countries in the same region would have similar dietary habits. You can also see that

- Cluster 2 contains countries with higher-than-average red meat consumption.
- Cluster 4 contains countries with higher-than-average fish consumption but low produce consumption.
- Cluster 5 contains countries with high fish and produce consumption.

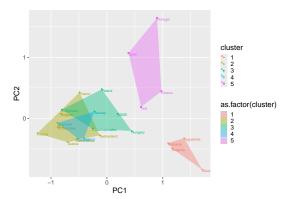

Visualising Clusters - Data preparation

```
princ <- prcomp(scaled_df) # Calculate the principal components of scaled df
nComp <- 2
                 # focus on the first two principal components
# project scaled_df onto the first 2 principal components to form a new
# 2-column data frame.
project2D <- as.data.frame(predict(princ, newdata=scaled_df)[,1:nComp])</pre>
# combine with `groups` and df$Country to form a 4-column data frame
hclust.project2D <- cbind(project2D, cluster=as.factor(groups), country=df$Country)
head(hclust.project2D)
##

```

Visualising Clusters - Finding the convex hull

chull(x, y = NULL) computes the convex hull of a given set of points. It returns a vector of indices of the unique points lying on the convex hull.

Visualising Clusters using ggplot

Assess whether a cluster represents true structure

To see if the cluster holds up under plausible variations in the dataset, <code>clusterboot()</code> from the <code>fpc</code> package uses bootstrap resampling to evaluate how stable a given cluster is.

- clusterboot() is an integrated function that both performs the clustering and evaluates the final produced clusters.
- It has interfaces to a number of R clustering algorithms, including both hclust and kmeans.
- clusterboot() uses the **Jaccard coefficient**, a similarity measure between sets A and B defined to be the ratio of the number of elements in the intersection of A and B over the number of elements in the union of A and B:

$$\mathsf{Jaccard}(A,B) = \frac{|A \cap B|}{|A \cup B|}$$

The basic general strategy

- Cluster the data as usual.
- ② Draw a new dataset (of the same size as the original) by resampling the original dataset with replacement (meaning that some of the data points may show up more than once, and others not at all). Cluster the new dataset.
- So For every cluster in the original clustering, find the most similar cluster in the new clustering (the one that gives the maximum Jaccard coefficient) and record that value.
 - If this maximum Jaccard coefficient is less than 0.5, then the original cluster is considered to be dissolved – it didn't show up in the new clustering.
 - A cluster that's dissolved too often is probably not a real cluster.
- Repeat steps 2-3 several times.

Judging the stability of a clustering algorithm

The *clustering* stability of each cluster in the original clustering is the *mean* value of its Jaccard coefficient over all the bootstrap iterations.

- *Unstable* if stability < 0.6
- Patterns are discovered but with low certainty if $0.6 \le \text{stability} \le 0.75$
- Highly stable possible real clusters if stability > 0.85

Running clusterboot()

As different clustering algorithms can give different stability values, even when the algorithms produce highly similar clusterings, <code>clusterboot()</code> can be used to find out how stable the clustering algorithm is.

```
## boot 3
## boot 4
## boot 5
## boot 6
## boot 7
## boot 8
## boot 10
## boot 11
## boot 12
## boot 13
```

Running clusterboot() (cont.)

We can use summary() to inspect the result from clusterboot():

```
summary(cboot.hclust$result)
##
Length Class
```

```
## Length Class Mode
## result 7 hclust list
## noise 1 -none- logical
## nc 1 -none- numeric
## clusterlist 5 -none- numeric
## partition 25 -none- numeric
## clustermethod 1 -none- character
## nccl 1 -none- numeric
```

Running clusterboot() (cont.)

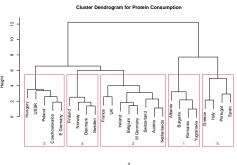

```
groups.cboot <- cboot.hclust$result$partition</pre>
print_clusters(df, groups.cboot, "Country")
## [1] "cluster 1"
## [1] "Albania"
                   "Bulgaria" "Romania" "Yugoslavia"
  [1] "cluster 2"
## [1] "Austria"
                   "Belgium" "France" "Ireland"
                                                            "Netherlands" "Switz
## [1] "cluster 3"
## [1] "Czechoslovakia" "E Germany" "Hungary"
                                                        "Poland"
                                                                        "USSR."
## [1] "cluster 4"
## [1] "Denmark" "Finland" "Norway" "Sweden"
## [1] "cluster 5"
## [1] "Greece" "Italy" "Portugal" "Spain"
```

Count how many times each cluster was dissolved

By default, clusterboot() runs 100 bootstrap iterations. # cboot.hclust\$bootbrd = number of times a cluster is desolved.

```
(values <- 1 - cboot.hclust$bootbrd/100)  # large values here => highly stable
## [1] 0.78 0.84 0.55 0.77 0.65
cat("So clusters", order(values)[5], "and", order(values)[4], "are highly stable"
```

cat("So clusters", order(values)[5], "and", order(values)[4], "are highly stable")
So clusters 2 and 1 are highly stable

d hclust (*, *ward.D2*)

Finding the number of clusters *k*

One simple heuristic for assessing the clustering results is to compute the total within sum of squares (WSS) for different values of k and look for an elbow in the curve.

The *centroid* of a cluster j with m elements is the mean value of all the points x_i in the cluster:

$$c_j = \frac{1}{m} \sum_{i=1}^m x_i$$

1. Calculate the WSS:

The WSS value of a cluster is the average squared distance of each point in the cluster from the cluster centroid, e.g., the WSS of the j^{th} cluster is:

$$WSS_{j} = \frac{1}{m} \sum_{i=1}^{m} \|x_{i} - c_{j}\|^{2}$$

2. Calculate the Total WSS:

If the total number of clusters is k then the total WSS is simply:

total WSS =
$$\sum_{i=1}^{k}$$
 WSS_i

The total WSS value will decrease as the number of clusters increases, because each cluster will be smaller and tighter.

The hope is that the rate at which the WSS decreases will slow down for k beyond the optimal number of clusters.

In other words, the graph of WSS versus k should flatten out beyond the optimal k, so the optimal k will be at the *elbow* of the graph.

3. Calculate the Calinski-Harabasz index:

The *Calinski-Harabasz index* (or CH index, for short) is another commonly used measure of cluster goodness.

To compute the CH index, we need to compute the following:

• The total sum of squares (TSS) – the sum of the squared distances of all the points from the centroid of the data. TSS is independent of the clustering. Given the centroid \bar{x} and for n data points:

$$TSS = \sum_{i=1}^{n} (x_i - \bar{x})^2$$

 The between sum of squares (BSS), which measures how far apart the clusters are from each other, is defined as BSS = TSS - WSS. A good clustering has a small WSS (all the clusters are tight around their centres) and a large BSS.

3. Calculate the Calinski-Harabasz index (cont.):

The *within-cluster variance W* is given by:

$$W = WSS/(n-k)$$

where n is the total number of data points and k is the number of clusters. The *between-cluster variance* B is given by:

$$\mathsf{B} = \mathsf{BSS}/(k-1)$$

3. Calculate the Calinski-Harabasz index (cont.):

The Calinski-Harabasz (CH) index is defined as:

$$CH = B/W$$

A good clustering should have a large ${\sf B}$ and a small ${\sf W}$ so we should try to maximise the CH index.

Finding *k* − Implementation in R

```
# Function to return the squared Euclidean distance of two given points x and y
sqr euDist <- function(x, y) {</pre>
    sum((x - y)^2)
}
# Function to calculate WSS of a cluster, represented as a n-by-d matrix
# (where n and d are the numbers of rows and columns of the matrix)
# which contains only points of the cluster.
wss <- function(clustermat) {
    c0 <- colMeans(clustermat)</pre>
    sum(apply( clustermat, 1, FUN=function(row) {sqr_euDist(row, c0)} ))
}
# Function to calculate the total WSS. Argument `scaled df`: data frame
# with normalised numerical columns. Argument `labels`: vector containing
# the cluster ID (starting at 1) for each row of the data frame.
wss total <- function(scaled df. labels) {
    wss.sum <- 0
    k <- length(unique(labels))</pre>
    for (i in 1:k)
        wss.sum <- wss.sum + wss(subset(scaled df, labels == i))
    wss.sum
}
```

Finding k – Implementation in R (cont.)

```
# Function to calculate total sum of squared (TSS) distance of data
# points about the (global) mean. This is the same as WSS when the
# number of clusters (k) is 1.
tss <- function(scaled df) {
   wss(scaled df)
}
# Function to return the CH indices computed using hierarchical
# clustering (function `hclust`) or k-means clustering (`kmeans`)
# for a vector of k values ranging from 1 to kmax.
CH index <- function(scaled df, kmax, method="kmeans") {
    if (!(method %in% c("kmeans", "hclust")))
        stop("method must be one of c('kmeans', 'hclust')")
    npts <- nrow(scaled_df)</pre>
    wss.value <- numeric(kmax) # create a vector of numeric type
    # wss.value[1] stores the WSS value for k=1 (when all the
    # data points form 1 large cluster).
    wss.value[1] <- wss(scaled df)
```

Finding k – Implementation in R (cont.)

Function CH_index continuing below...

```
if (method == "kmeans") {
    # kmeans
    for (k in 2:kmax) {
        clustering <- kmeans(scaled_df, k, nstart=10, iter.max=100)</pre>
        wss.value[k] <- clustering$tot.withinss
    7
} else {
    # hclust
    d <- dist(scaled df, method="euclidean")</pre>
    pfit <- hclust(d, method="ward.D2")</pre>
    for (k in 2:kmax) {
        labels <- cutree(pfit, k=k)</pre>
        wss.value[k] <- wss_total(scaled_df, labels)
    }
bss.value <- tss(scaled df) - wss.value # this is a vector
B \leftarrow bss.value / (0:(kmax-1))
                                            # also a vector
W <- wss.value / (npts - 1:kmax)
                                             # also a vector
data.frame(k = 1:kmax, CH_index = B/W, WSS = wss.value)
```

Code to plot the CH index vs k

```
library(gridExtra)

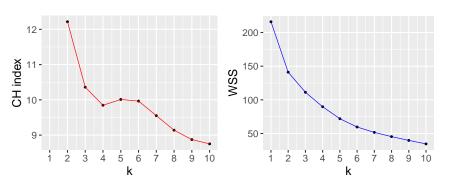

# calculate the CH criterion
crit.df <- CH_index(scaled_df, 10, method="hclust")

fig1 <- ggplot(crit.df, aes(x=k, y=CH_index)) +
    geom_point() + geom_line(colour="red") +
    scale_x_continuous(breaks=1:10, labels=1:10) +
    labs(y="CH index") + theme(text=element_text(size=20))

fig2 <- ggplot(crit.df, aes(x=k, y=WSS), color="blue") +
    geom_point() + geom_line(colour="blue") +
    scale_x_continuous(breaks=1:10, labels=1:10) +
    theme(text=element_text(size=20))</pre>
```

Code to plot the CH index vs k (cont.)

grid.arrange(fig1, fig2, nrow=1)

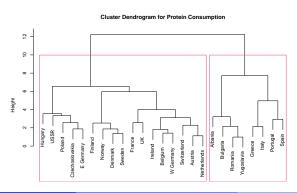

Looking at the figure, we see that the CH criterion is maximised at k = 2, with another local maximum at k = 5.

Output from hclust() with k = 2

Using k = 2, the output from hclust() is:

(Note that we don't need to recompute pfit <- hclust(d,
method="ward.D2"))</pre>

plot(pfit, labels=df\$Country, main="Cluster Dendrogram for Protein Consumption")
rect.hclust(pfit, k=2)

Semester 2, 2024

kMeans procedure

Cluster Dendrogram

Repeat steps 3 and 4 until the points stop moving, or you have reached a maximum number of iterations.

The kmeans() function

The function to run k-means in R is kmeans (). The output of the function includes :

- the cluster labels:
- the centres (centroids) of the clusters;
- the total sum of squares, total WSS, total BSS, and the WSS of each cluster.

```
kbest.p <- 5
# run kmeans with 5 clusters, 100 random starts, and 100
# maximum iterations per run.
kmClusters <- kmeans(scaled_df, kbest.p, nstart=100, iter.max=100)</pre>
```

Centres and sizes of the 5 Clusters

```

```

kmeansruns() for picking k

We can use the CH_{index} () function to find the optimal k value that maximises the CH index. Alternatively, we can use kmeansruns() (from the fpc package) which calls kmeans() over a range of k and estimates the best k.

kmeansruns() has two criteria:

- The Calinski-Harabasz Index ("ch"), and
- The average silhouette width ("asw")

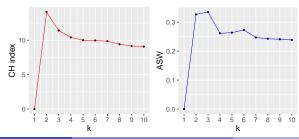

It's a good idea to plot the criterion values over the entire range of k, since you may see evidence for a k that the algorithm didn't automatically pick.

For more information about silhouette clustering, see http://mng.bz/Qe15

kmeansruns() for picking k (Cont.)

```
library(fpc)
kmClustering.ch <- kmeansruns(scaled_df, krange=1:10, criterion="ch")
kmClustering.ch$bestk
## Γ17 2
kmClustering.asw <- kmeansruns(scaled_df, krange=1:10, criterion="asw")</pre>
kmClustering.asw$bestk
## [1] 3
# Compare the CH values for kmeans() and hclust().
print("CH index from kmeans for k=1 to 10:")
## [1] "CH index from kmeans for k=1 to 10:"
print(kmClustering.ch$crit)
print("CH index from hclust for k=1 to 10:")
## [1] "CH index from hclust for k=1 to 10:"
hclusting <- CH_index(scaled_df, 10, method="hclust")
print(hclusting$CH_index)
## [1] NaN 12.215107 10.359587 9.847229 10.011797 9.964967 9.552301 9.139
```

Code to plot CH and ASW against k

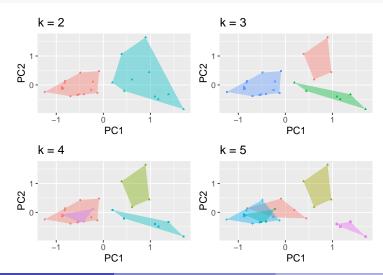

Visualisation of clusterings from kmeans

```
fig <- c()
kvalues \leftarrow seq(2,5)
for (k in kvalues) {
  groups <- kmeans(scaled_df, k, nstart=100, iter.max=100)$cluster
  kmclust.project2D <- cbind(project2D, cluster=as.factor(groups),</pre>
                              country=df$Country)
  kmclust.hull <- find convex hull(kmclust.project2D, groups)
  assign(paste0("fig", k),
    ggplot(kmclust.project2D, aes(x=PC1, y=PC2)) +
    geom point(aes(shape=cluster, color=cluster)) +
    geom_polygon(data=kmclust.hull, aes(group=cluster, fill=cluster),
                 alpha=0.4, linetype=0) +
    labs(title = sprintf("k = %d", k)) +
    theme(legend.position="none", text=element_text(size=20))
```

Visualisation of clusterings from kmeans

library(gridExtra)
grid.arrange(fig2, fig3, fig4, fig5, nrow=2)

Clustering take-aways

- The goal of clustering is to discover or draw out similarities among subsets of your data.
- In a good clustering, points in the same cluster should be more similar (nearer) to each other than they are to points in other clusters.
- When clustering, the units used in the variables matter. Different units cause different distances and potentially different clusterings.
- Ideally, you want a unit change in each coordinate to represent the same degree of change. One way to approximate this is to transform all the columns to have a mean value of 0 and a standard deviation of 1.0, for example by using the function scale().

Clustering take-aways (Cont.)

- Clustering is often used for data exploration or as a precursor to supervised learning methods.
- Like visualisation, it's more iterative and interactive, and less automated than supervised methods.
- Different clustering algorithms will give different results. You should consider different approaches, with different numbers of clusters.
- There are many heuristics for estimating the best number of clusters.
 Again, you should consider the results from different heuristics and explore different numbers of clusters.
